Homework 6: Java Flow-Directed Inliner

A grammar for MicroJava in JavaCC notation is on the CS 565 webpage. The goal of the homework is to write a MicroJava optimizer which inlines some method calls. The idea is to do flow analysis in the sense of OOTS Chapter 5 (in which flow analysis is known as "type inference"), and then use the computed information as the basis for replacing method calls with inlined code. You should only inline method calls for which the flow analysis has determined that there is a *unique* target method. There are many possible strategies for doing this, and your task is to invent one and implement it.

Ideally, the output language would be machine code. To save you from the trouble of writing all of an optimizing compiler, the output language is MicroJava.

So, use JTB/GJ and JavaCC and write in Java one or more visitors which transforms a MicroJava program to a MicroJava program in such a way that some method calls get inlined. You can assume that the MicroJava program can be compiled by javac.

Your main file should be called `Optimize.java`, and if `Prg.java` contains a program to be optimized, then

```
java Optimize < Prg.java > OptimPrg.java
```

creates the program `OptimPrg.java` which has the same behavior as `Prg.Java`, and which is like `Prg.Java`, except that some method calls have been inlined.
